

HEALTHCARE ENTERPRISE SaaS

UX DESIGN

2024-2025

Rave Support Portal

Redesigning a fragmented clinical trial support system into a unified, intelligent workspace — so healthcare operations teams spend less time navigating and more time doing.

MY ROLE	DOMAIN
Senior UX Designer	Healthcare / Clinical Trials
PLATFORM	ORGANISATION
Enterprise SaaS — Web	Roche / Genentech

PROJECT OVERVIEW

One platform for all Rave clinical trial support

Genentech's clinical operations teams rely on Rave — a clinical data management platform — to run global trials. The Rave Support Portal (RSP) is the internal gateway through which coordinators, site managers, and IT admins request account access, manage user permissions, and handle study configuration across dozens of concurrent protocols.

Before the redesign, users navigated a fragmented set of tools, email chains, and ticket systems — all with zero contextual guidance and no single source of truth. RSP was designed to consolidate these workflows into one intelligent, enterprise-grade portal.

12+

Form types consolidated into one portal

User roles — Coordinators, IT Admins, Site Managers

Global

Multi-site clinical trial environments

1

Unified workspace replacing scattered systems

The workflows were fragmented, silent, and blind

Discovery sessions and workflow walkthroughs revealed six recurring failure points across all user types.

01 No single entry point Users juggled multiple tools — email, ticketing systems, and legacy portals — to complete what should be a single workflow. There was no unified home.	02 Zero in-form guidance Forms offered no contextual help. Users frequently misunderstood fields like 'Protocol Number' or 'Type of Access', leading to submission errors and re-work.	03 No access to recent or frequent tasks Every session started from scratch. Users who regularly filled the same forms had no way to bookmark, pin, or quickly return to frequently used workflows.
04 Missed cross-form dependencies After submitting one form, users were unaware that related forms also needed to be filled. Critical steps in multi-form workflows were often skipped.	05 Updates buried or missed System alerts, policy changes, and critical notifications were sent via email — easily missed by users who only checked the portal intermittently.	06 High cognitive load for power users Coordinators managing multiple studies had to mentally track which forms they'd submitted, for which protocols, with no dashboard-level visibility.

DESIGN DECISIONS

Four decisions that changed the experience

Each design decision was rooted in a specific pain point. Here's how we solved them.

01 / 04

PROACTIVE COMMUNICATION

Updates and alerts — visible the moment you log in

Before users even reach a form, they now see system-level notifications, policy changes, and pending action items directly on the login-to-dashboard transition. Nothing is buried.

- Critical alerts surfaced at session start, not in email
- Personalised welcome + notification badge on first view
- AI assistant available immediately — not a secondary feature
- Eliminates the 'I didn't know' failure mode for important updates

02 / 04

FAVOURITES & QUICK ACCESS

Bookmark your most-used forms for instant access

Power users — coordinators managing 5–10 active protocols — need to repeat workflows constantly. Pinned favourites and 'Your Creations Today' give them a personalised starting point every session.

- Pin any form to favourites with a single click (heart icon)
- Homepage surfaces pinned forms in a persistent row
- 'Your Creations Today' tracks same-session submissions
- Reduces navigation depth from 4+ clicks to 1

03 / 04

CONTEXTUAL AI ASSISTANCE

Dynamic, field-aware help — right where the user needs it

The integrated AI assistant doesn't just answer general questions — it detects which field the user is on and proactively offers contextual guidance. It surfaces definitions, upload instructions, and related quick links without the user having to ask.

- AI panel opens alongside the form — no modal interruption
- Context shifts dynamically as the user moves between fields
- Pre-loaded FAQs based on current form type (e.g. 'What is Protocol Number?')
- Suggested quick-action chips reduce typing load
- Supports enterprise compliance by surfacing policy reminders inline

04 / 04

POST-SUBMISSION INTELLIGENCE

After one form, you're guided to the next

Many workflows in clinical trial management are multi-step but non-obvious. After a successful submission, the system now suggests related forms the user likely needs to fill next — turning isolated transactions into connected workflows.

- Personalised 'Suggestions for you' appear on the success screen
- Suggestions based on current form type and submission history
- Eliminates incomplete workflow chains — a major compliance risk
- Drives task completion without adding cognitive load

USER FLOW

End-to-end walkthrough

From login to form submission to next-step suggestion — the complete flow as a clinical trial coordinator experiences it.

Login

Personalised welcome with AI assistant already active. Alerts and notifications visible before entering the portal.

Homepage Dashboard

Pinned favourites, today's submissions, and contextual onboarding banner. A single, scannable home base.

Form + AI Panel

Internal User Account form with AI help panel open. Users see contextual guidance without leaving the form.

Field-Level AI Help

AI dynamically explains 'Protocol Number' when the user focuses the field — with supporting image and description.

Dynamic Dropdown + AI

Type of Access dropdown opens inline. AI panel simultaneously explains each option — reducing selection errors.

Submission + Suggestions

Request confirmed with a friendly success state. Immediately followed by personalised form suggestions to continue the workflow.

UX STRATEGY

Principles that shaped every decision

Enterprise SaaS design requires thinking beyond the screen — balancing user efficiency with operational correctness.

Reduce before you add

Every feature was evaluated against cognitive load. If it didn't reduce steps or clarify a decision, it didn't ship.

Proactive over reactive

Surface information before users ask for it — alerts at login, AI context on field focus, suggestions after submission.

Personalisation as productivity

Favourites and recent history aren't convenience features — they're critical for power users managing 10+ concurrent protocols.

Compliance by design

In regulated healthcare environments, reducing errors is non-negotiable. Inline AI guidance and contextual dropdowns directly support compliance outcomes.

OUTCOMES

Measurable impact on operations

Key improvements across workflow efficiency, compliance support, and user satisfaction following rollout.

↓ 60%

Reduction in form submission errors

Attributed to inline AI field guidance and contextual dropdown explanations

↑ 3x

Faster access to frequently used forms

Pinned favourites reduced average navigation depth from 4 steps to 1

↓ 40%

Drop in support tickets for form guidance

The AI assistant deflected routine 'how do I fill this?' queries

↑ 2x

Multi-form workflow completion rate

Post-submission suggestions drove users to complete related workflows they'd previously missed

QUALITATIVE IMPACT

Onboarding time for new coordinators dropped significantly — the AI assistant effectively reduced the need for peer-to-peer 'how-to' training on forms.

Operations managers reported fewer escalation requests, as users could now self-serve answers to questions that previously required a support contact.

Cross-team alignment improved — with a single portal as the source of truth, IT admins and study coordinators operated from the same workflow context.

REFLECTION

What enterprise healthcare UX taught me

Compliance shapes design constraints

In regulated environments, you can't just optimise for delight. Every design decision carries operational and compliance weight. The AI guidance wasn't a nice-to-have — it was a risk mitigation tool.

Power users define the baseline

Designing for the occasional user produces interfaces that feel friendly but inefficient. In enterprise SaaS, optimising for power users — with progressive disclosure for new ones — is the right strategy.

Proactive design reduces noise

Surfacing the right information before users ask for it — at login, during form filling, after submission — is infinitely more effective than reactive help models like FAQs and documentation.
